

FOR AFFILIATE MANAGERS & TECH SUPPORT

Param Decoder

How to use it

Paste a link, get the answer. A five-minute walkthrough of every mode.

START HERE

Which mode do I use?

You're holding a link, a code, or a postback URL and something isn't working. Match what you have to a mode:

One offer or **checkout link**

"Why isn't this tracking?" · QA before launch

Inspect

Two links to compare

"It worked last week, now it doesn't"

Compare

A whole **column of links**

Pre-launch campaign audit

Batch

A tracker's **postback URL**

"Conversions aren't showing in Voluum"

Postback

A **decline code** from a failed charge

A customer's payment failed — why?

Decline

Read & repair one link.

Paste any offer or checkout URL — even messy, encoded, or with a Base64 redirect — and you get a labelled table back, one row per param:

- **aff_id** (empty) — affiliate earns no commission · one-click fix offered
- **subid2** **clk_abc123** — click ID · tracker will credit the sale
- **utm_source** — unrecognised param · did you mean utm_source?

Fix the red flag inline, then **copy the clean rebuilt link** — or the **ticket-ready diagnosis** — straight into the ticket.

One vs one, or all at once.

COMPARE

Why does one track and the other doesn't?

A: aff_id=162939 subid2=abc123
B: aff_id=162939 subid2=(empty)

Same affiliate — but B's click ID is missing, so its tracker goes dark.
That's the whole answer.

BATCH

Audit a campaign in one paste

Drop a spreadsheet column of links → a **green/red** table. **Pass** = valid aff_id, no broken params. **Fail** = at least one error. Every failed row links into Inspect. CSV export + bulk aff_id fill.

Set up a tracker postback right.

A postback is a URL BuyGoods fires when a sale completes — it's how the affiliate's tracker learns a conversion happened. If the tokens are wrong, the tracker records nothing, **even though the sale went through**. Paste their postback URL; the tool flags which tokens are present, missing, or wrong — then copy the corrected template:

- **Voluum** — `cid` = click ID, `payout` = revenue, `txid` = order ID.
- **CPV Lab** — `subid` = click ID, `revenue` = payout.
- **AnyTrack** — `click_id`, `value`, `transactionId`.

Each template is sourced from the tracker's own docs, with a copy button.

Explain a failed payment.

A decline code comes from the **transaction**, not a URL — in BuyGoods, the transaction record shows the raw code. Paste exactly what appears there:

```
→ do_not_honor (Braintree 2000)
type:  hard — permanent for this card
action: Ask the customer to contact their bank or use a different card. Don't retry.
```

SOFT

Temporary

A retry can still work — insufficient funds, issuer busy.

HARD

Permanent for this card

Expired, lost / stolen, do-not-honor — ask for another card.

What the colours & badges mean.

Status flags

- **Error** — broken; usually a missing `aff_id` or unfilled token. Fix before it goes live.
- **Warning** — present but suspicious: a UTM with spaces, a leftover template variable.
- **OK** — recognised and valid; nothing to do.
- **Heads-up** — info: this param carries the click ID, not commission.

Trust badges — who vouches for the meaning

- CONFIRMED** Set by the team — rely on it.
- INFERRED** The tool's best guess — treat as provisional.
- NOTED** You saved this meaning on this device.

YOUR FIRST TASK

Open it and paste a link.

Drop one of your affiliate's links into Inspect. Look for the **red flag** first — if `aff_id` is missing or empty, that's your answer. Everything else is context.

And paste freely — nothing you enter is ever sent, stored, or logged.
